## Abstract

TPC-173–181 test two interfaces left open by MVP7. The structural side freezes every TPC-133–172 manuscript, maps every occurrence-adjacent claim, and finds no theorem statement satisfying the complete source-locked local actual-occurrence edge contract. Consequently the largest defensible local family in that declared corpus is empty. Its gluing coverage is 0 of 2988 archived cuts. Empty eligibility does not certify actual active support, and the five-field archive address is not a canonical physical representative. The extraction cell for this corpus is stopped, but the occurrence-augmented architecture remains open and not-testable.

The phase side source-locks the fact  $h_0 = 2$ , but finds no named physical atom, phase value, or production packet-coordinate row. Moreover, an almost-every-phase theorem cannot select a prescribed singleton: a full-measure good set may omit that point. Thus the uncontrolled metric-to-atom method is stopped in its exact scope. The source-backed selector remains not-testable, and the two direct pointwise fixed-atom targets remain open.

MVP8 imports these results without promoting their quantifiers. Its verdict is NOT-TESTABLE, with first missing object

H1.source\_backed\_local\_occurrence\_edge\_family.

The seven-node structural/physical blocker antichain is unchanged. The TPC-170 phase-metric powers remain ineligible for a named-atom endpoint charge. No program-positive L2, strict 1/400, prime-pair lower bound, or twin-prime theorem is proved.

## 1 Dynamic imported state

MVP7 ended with three structural roots and four physical registry roots [4]. The present classifier does not assume that the planned TPC-173–181 route succeeded. It reads the canonical artifacts of those papers and rejects any mismatch in family cardinality, coverage, support status, representation status, phase identity, selector status, or pointwise-route status. The resulting eight source hashes are integrity locks only.

Let

$$\mathcal{B}_{H1} = \{\text{source\_backed\_local\_occurrence\_edge\_family}, \\ \text{actual\_active\_support\_certificate}, \\ \text{canonical\_minimal\_representation\_certificate}\}. \quad (1)$$

The physical roots are

$$\mathcal{B}_{H9} = \{\text{literal\_weight}, \text{phase\_cell}, \text{endpoint}, \text{normalization}\}_{\text{registry}}. \quad (2)$$

All seven nodes have status NOT-TESTABLE. Their roles differ: the first three are structural certificates and the last four are literal data registries with decay axis NONE.

## 2 The scoped structural stop

TPC-173 freezes the contiguous theorem corpus

$$\mathcal{C}_{133:172} = \{\text{the unique } \texttt{main.tex} \text{ of TPC-}n : 133 \leq n \leq 172\}. \quad (3)$$

Its forty files are partitioned into thirty mapped but disqualified sources and ten reviewed files with no candidate; no file is left unmapped. A qualifying claim must have resolving theorem and formula locators, a nonempty derivation, an actual local-occurrence conclusion, the five-field production cut address, an exact edge weight, fixed- $h_0 = 2$  lineage, and physical-normalization lineage.

**Proposition 2.1** (Declared-corpus maximality). *Relative to  $\mathcal{C}_{133:172}$ , the largest source-locked local actual-occurrence edge family has cardinality zero.*

*Proof.* TPC-173 maps every candidate and obtains zero qualifying claims. TPC-174 makes the required witness contract explicit, while keeping its two-edge nonvacuity fixture synthetic. TPC-175 requires every production row to import a qualifying TPC-173 claim. Hence any nonempty admissible family would contain a row whose source claim is in the empty qualifying set, a contradiction [5–7].  $\square$

The conclusion of [proposition 2.1](#) is closed-world. It is not

$$\text{“no local actual-occurrence edge exists in mathematics.”} \quad (4)$$

A new source corpus or a genuinely new theorem can define a new extraction cell.

TPC-176 applies the formal gluing interface only to the proved local family. The exact coverage ledger is

$$\#\text{proved local edges} = 0, \quad \#\text{covered cuts} = 0, \quad \#\text{unmatched cuts} = 2988. \quad (5)$$

There are no duplicates because there are no eligible rows. This does not satisfy the nonempty local-totality hypotheses of the TPC-165 gluing theorem [2, 8].

## 3 Vacuity is not a certificate

The other two roots in (1) are independent of local edge existence. TPC-177 and TPC-178 therefore do not close them by vacuity.

**Proposition 3.1** (Support firewall). *Zero sourced carriers do not prove an actual active-support certificate. In particular, the statement*

$$\forall o \in \emptyset, \quad c_{\text{phys}}(o) \neq 0 \quad (6)$$

*is vacuously true but does not identify the required production carrier or its nonzero literal coefficient.*

*Proof.* The target certificate is existentially anchored: it must source-lock the actual carrier and then prove nonvanishing of its literal coefficient. Universal truth on an empty test domain supplies neither object. The separate H9 literal-weight registry also remains missing; it cannot be inferred from a support predicate [9].  $\square$

Likewise, TPC-164’s unique minimum separating key

$$(\ell, k, \text{native\_d}, j_L, j_K) \quad (7)$$

is an archive address. TPC-178 finds no actual carrier on which to test a physical quotient or minimal parent. Thus address injectivity does not imply canonical physical representation [1, 10].

TPC-179 integrates these facts. The corpus extraction cell is STOP-SCOPED, while the global occurrence-augmented architecture is OPEN/NOT-TESTABLE. The three-root antichain (1) is unchanged [11].

## 4 The production phase registry

TPC-180 separates one positive data fact from the missing phase registry:

$$h_0 = 2 \text{ is source-backed, } \alpha_{\text{phys}}, \text{ loc}(\alpha_{\text{phys}}), \mathcal{P}_{\text{prod}} \text{ are absent.} \quad (8)$$

Here  $\mathcal{P}_{\text{prod}}$  is the exact source-locked list of production packet coordinates. The census has no named atom ID, no phase value modulo one, and no packet-coordinate row. Consequently

$$\text{H9.phase\_cell\_registry} = \text{NOT-TESTABLE}, \quad \text{decay\_axis} = \text{NONE.} \quad (9)$$

Neither the value  $h_0 = 2$  nor a future registry would manufacture a cancellation exponent [12].

The strongest arithmetic import remains the TPC-170 theorem: for Lebesgue-almost every fixed phase, eventually every declared packet and every prefix on the prescribed schedule obeys the phase-metric bound, with powers  $X^{-\delta}$  for every  $\delta < 1/4$  in the polylogarithmic regime [3]. The exceptional null set depends on the entire schedule.

## 5 The selector obstruction

**Theorem 5.1** (Singleton nonimplication). *Let  $\alpha_\star$  be any prescribed point of the phase torus. The assertion that a measurable good set has full Lebesgue measure does not imply that it contains  $\alpha_\star$ .*

*Proof.* The set

$$\mathbb{T} \setminus \{\alpha_\star\} \quad (10)$$

has full Lebesgue measure and omits  $\alpha_\star$ . Equivalently, a measure-zero exceptional set may be precisely the prescribed singleton. Applying this logical model to the TPC-170 Borel–Cantelli conclusion shows that the metric theorem alone does not prove avoidance of its schedule-dependent limsup exceptional set at a named physical atom.  $\square$

TPC-181 therefore records

$$\begin{aligned} \text{phase\_metric\_uncontrolled\_atomic} &= \text{STOP-SCOPED}, \\ \text{phase\_metric\_source\_backed} &= \text{NOT-TESTABLE.} \end{aligned} \quad (11)$$

The first line is a scoped logical obstruction. The second can be reopened by a source-locked named phase, its exact production schedule, and a theorem that this point avoids the corresponding exceptional set. A direct pointwise fixed-phase theorem bypasses the metric selector entirely [13].

## 6 Typed routes and endpoint ledger

Architecture and arithmetic methods remain disjoint. The current route cells are summarized in [table 1](#).

Table 1: MVP8 route cells. A scoped cell stop does not stop its parent architecture or an independent theorem method.

| Cell                                  | State             | Exact meaning                                                       |
|---------------------------------------|-------------------|---------------------------------------------------------------------|
| Occurrence-augmented architecture     | OPEN/NOT-TESTABLE | Still lacks all three structural roots.                             |
| TPC-133–172 edge extraction           | STOP-SCOPED       | No qualifying source claim in that frozen corpus.                   |
| Uncontrolled metric-to-atom promotion | STOP-SCOPED       | Almost-every phase does not select a prescribed singleton.          |
| Source-backed metric selector         | OPEN/NOT-TESTABLE | Named atom, production schedule, and avoidance theorem are missing. |
| Bad-endpoint pointwise fixed atom     | OPEN              | Parent-ready O161 arithmetic target.                                |
| Direct additive-twist fixed atom      | OPEN              | Parent-ready O161 arithmetic target.                                |

Endpoint Ledger V5 keeps the metric and named-atom powers separate:

$$\sigma_{\text{metric}} = \{\delta : \delta < 1/4\}, \quad \sigma_{\text{named}} = 0, \quad \sigma_{\text{req}} = \frac{1}{400}. \quad (12)$$

The first entry has phase quantifier `LEBESGUE_AE_FIXED_PHASE`, so it is not eligible for the second entry. Literal coefficients, atomic normalization, actual support, canonical/minimal representation, and strict endpoint slack remain not-testable. Therefore the strict 1/400 charge is unpaid.

All six quantifier axes remain unpromoted:

| axis     | proved                       | required                   |
|----------|------------------------------|----------------------------|
| carrier  | explicit packet corridor     | actual fixed- $h_0$ packet |
| phase    | Lebesgue-a.e. fixed phase    | named fixed atom           |
| endpoint | all shell prefixes           | deterministic all prefixes |
| scale    | eventual prescribed schedule | deterministic all scales   |
| decay    | phase-metric $X$ -power      | fixed-atom $X$ -power      |
| support  | actual core                  | actual active support      |

(13)

## 7 MVP8 decision

**Theorem 7.1** (MVP8). *For the source-locked TPC-172 and TPC-175–181 artifacts, the current route verdict is*

$$\boxed{\text{NOT\_TESTABLE}}. \quad (14)$$

*The first missing object is `H1.source_backed_local_occurrence_edge_family`, and the minimal not-testable antichain is exactly  $\mathcal{B}_{\text{H1}} \cup \mathcal{B}_{\text{H9}}$ . The two O161 pointwise fixed-atom targets remain open and parent-ready.*

*Proof.* [Propositions 2.1](#) and [3.1](#) and the TPC-178 representation audit leave all three H1 roots not-testable. Equations (9) and (11) leave every H9 root missing and stop only one arithmetic method cell. No architecture infeasibility theorem or complete route-universe theorem is imported. The ledger (12) has no named-atom power and no strict endpoint slack. The classifier therefore selects NOT-TESTABLE, preserving the declared first-root order and both disjoint pointwise targets.  $\square$

The next structural object is not another hash or schema: it is a new explicit source corpus or a new theorem-backed local occurrence edge. The next phase object is a source-locked named atom together with a schedule-specific avoidance theorem; absent that bridge, work returns to the two pointwise O161 targets.

## 8 Claim firewall

The batch contributes L0 executable contracts and diagnostics, and two L1 scoped obstructions: declared-corpus source exhaustion and the metric-to-singleton nonimplication. It contributes no new production occurrence family, active-support certificate, canonical physical representation, named fixed-atom theorem, or program-positive L2 estimate.

In particular, this paper does not prove RH, a strict 1/400 endpoint gain,  $B_{2,\delta}(X) = o(X)$ , a prime-pair lower bound, the twin-prime conjecture, or infinitude of twin primes.
