

The Two Pointwise Fixed-Atom Parents: A Source-Locked Interface Comparison

Liang Wang

Abstract

The two O161 parents have the same six-axis target signature, but different literal normalizations (q/T versus q/N). After explicitly locking the common summand, specialization $N=T$ proves direct twist implies the bad-endpoint target. The reverse implication is not established. The narrower bad-endpoint parent is selected first. The classification is `ROUTE_DECISION_L1`; no L2 arithmetic progress or endpoint credit is claimed.

1 Frozen target

The selected route is `0161.bad_endpoint_pointwise_fixed_atom` [1]. The required signature is actual fixed- h_0 packet, named fixed atom, deterministic every prefix, deterministic every scale, fixed- X power at that atom, and actual active support. Throughout $h_0 = 2$ is only a source-backed data fact.

2 Exact result

Theorem 1. *Source-locked specialization theorem: on the identical actual-core summand, with uniform constants, exponent, atom, scale range, and endpoint range, the all-prefix direct estimate with normalization q/N specializes separately at $N=T$ for every bad endpoint T . Thus direct implies bad endpoint. The reverse implication is not established.*

Proof. Fix any T in the bad-endpoint set. The direct hypothesis is uniform for every admissible prefix N , so take $N=T$. The summand, atom, constant and exponent are unchanged, and $q/N=q/T$. This proves the bad-endpoint bound for each such T . The source graph contains no reverse edge and the bad hypothesis has the smaller endpoint domain; we therefore record the reverse implication as not established, not false. $\square$

The smallest missing literal theorem is `UNIFORM_NAMED_ATOM_BAD_ENDPOINT_PREFIX_POWER_SAVING`.

3 Scoped stop and claim firewall

No new scoped stop is declared in this paper.

The result is L0/L1 only. Phase averages and Lebesgue-almost-every phase are not named atoms. Fixed $h_0 = 2$ is not decay. Archive addressing is not canonical physical representation, and empty-domain truth is not actual active support. The named-atom endpoint charge is zero, so the strict 1/400 budget is unpaid. We claim no program-positive L2, prime-pair lower bound, or twin-prime theorem.

4 Reproducibility

The adjacent JSON payload records the full six-axis signature, source lock, typed result, exact scoped-stop cell, endpoint ledger, and claim firewall. The audit artifact contains eight true mutation-rejection assertions.
