

A Literal Contract for the Bad-Endpoint Pointwise Fixed-Atom Target

Liang Wang

Abstract

The bad-endpoint target is frozen as a q/T-normalized cumulative actual-core sum at the prescribed atom, uniformly over every prefix endpoint and deterministic scale. TPC-159 supplies only the complement of its dyadic shadow; TPC-169 supplies all prefixes only in phase L2. Neither matches the contract. The classification is `CONTRACT_L0_L1`; no L2 arithmetic progress or endpoint credit is claimed.

1 Frozen target

The selected route is `0161.bad_endpoint_pointwise_fixed_atom` [1]. The required signature is actual fixed- h_0 packet, named fixed atom, deterministic every prefix, deterministic every scale, fixed- X power at that atom, and actual active support. Throughout $h_0 = 2$ is only a source-backed data fact.

2 Exact result

Theorem 1. *Contract separation theorem: an almost-endpoint pointwise statement and an all-endpoint phase-metric statement are each strictly weaker in one required axis than the named-atom all-prefix contract.*

Proof. The locked TPC-171 target requires `NAMED_FIXED_ATOM` and every prefix. TPC-159 has the named pointwise axis but deletes its dyadic shadow. TPC-169 restores every prefix but has phase axis `L2_PHASE_MAXIMAL`. Each source therefore mismatches one literal required axis, so neither artifact instantiates the frozen contract. $\square$

The smallest missing literal theorem is `POINTWISE_NAMED_ATOM_CONTROL_INSIDE_TPC159_DYADIC_SHADOW`.

3 Scoped stop and claim firewall

No new scoped stop is declared in this paper.

The result is L0/L1 only. Phase averages and Lebesgue-almost-every phase are not named atoms. Fixed $h_0 = 2$ is not decay. Archive addressing is not canonical physical representation, and empty-domain truth is not actual active support. The named-atom endpoint charge is zero, so the strict 1/400 budget is unpaid. We claim no program-positive L2, prime-pair lower bound, or twin-prime theorem.

4 Reproducibility

The adjacent JSON payload records the full six-axis signature, source lock, typed result, exact scoped-stop cell, endpoint ledger, and claim firewall. The audit artifact contains eight true mutation-rejection assertions.
