

Integration of the Two Pointwise Fixed-Atom Audits

Liang Wang

July 2026

Abstract

The bad-endpoint route reduces exactly to fixed-atom local oscillation; the direct route requires pointwise arithmetic beyond Parseval. Size-only and uncontrolled metric-to-atom methods are scoped stops, not route stops. Neither parent is closed and the named-atom endpoint ledger remains at zero. The classification is `INTEGRATION_L1`; no L2 arithmetic progress or endpoint credit is claimed.

1 Frozen target

The selected route is `BOTH_0161_POINTWISE_PARENTS` [1]. The required signature is actual fixed- h_0 packet, named fixed atom, deterministic every prefix, deterministic every scale, fixed- X power at that atom, and actual active support. Throughout $h_0 = 2$ is only a source-backed data fact.

2 Exact result

Theorem 1. *Integrated frontier theorem: all new implications are deterministic L1 interface results. No literal physical coefficient theorem, actual-support certificate, canonical representation, or fixed-atom power has been added.*

Proof. The imported verdicts are: TPC-188 switches after the size-only and uncontrolled metric methods fail in scope; TPC-189 freezes the direct contract; TPC-190 stops Parseval-to-atom only. Each payload has `L2=false`, zero named-atom credit, and no route-stop flag. Therefore both theorem nodes stay open while precisely the three named method cells are stopped. $\square$

The smallest missing literal theorem is `LITERAL_FIXED_ATOM_ARITHMETIC_CANCELLATION`.

3 Scoped stop and claim firewall

No new scoped stop is declared in this paper.

The result is L0/L1 only. Phase averages and Lebesgue-almost-every phase are not named atoms. Fixed $h_0 = 2$ is not decay. Archive addressing is not canonical physical representation, and empty-domain truth is not actual active support. The named-atom endpoint charge is zero, so the strict 1/400 budget is unpaid. We claim no program-positive L2, prime-pair lower bound, or twin-prime theorem.

4 Reproducibility

The adjacent JSON payload records the full six-axis signature, source lock, typed result, exact scoped-stop cell, endpoint ledger, and claim firewall. The audit artifact contains eight true mutation-rejection assertions.
